# High-Brilliance Micro-Focus X-ray Sources for Diffractometry

T. Samtleben, J. Wiesmann, B. Hasse, J. Graf, C. Michaelsen - Incoatec GmbH, Geesthacht, Germany

# Incoatec Microfocus Source I $\mu$ S and 2D Montel Optics

The  $I\mu S$  is the perfect upgrade for equipment in X-ray diffractometry. It combines the advantages of a sealed-tube system with the superior data quality of conventional rotating anode systems. The  $\mu$ S is also included in the new equipment of Bruker AXS: for SAXS in the NANOSTAR and for SC-XRD in the D8 QUEST and VENTURE solutions for crystallography. The  $\mu$ S consists of a microfocus source and a specially designed multilayer optics named Quazar.

### The source

- high brilliance & best spectral purity
- Cu, Mo, Cr and Ag radiation available ■ air cooled
- $\blacksquare$  < 40  $\mu$ m spot size at the anode
- convenience of sealed-tube
- high voltage generator

- Quazar Optics
- 2-dim beam shaping
- collimating, focussing or collimating + focusing (hybrid)
- patented housing for high stability and easy alignment
- motorized alignment (optional)

- up to 60 % more flux due to improved optical design
- for Cu, Mo & Ag
- component recognition
- improved safety features
- compliant with Machinery Directive 2006/42/EC

(data from A. Heine, Philipps University Marburg, Germany)

# I $\mu$ S for Ag Radiation: Best for High-Pressure Crystallography

The small beam cross-section of the  $I\mu$ S for Mo and Ag radiation reveals what an interesting alternative they are to sealed tube sources for diffraction studies on single crystals and powders using diamond anvil cells for high-pressure crystallography. The focused beam reduces part of the background caused by scattering at the gasket, thus improving the signal-to-noise ratio.

Charge density study on oxalic acid. Multipole refine-ment : No. of unique 3784; Refinement incl. 2450;R(F) 0,036; N(ref)/N(var) 23.1; H-Atoms constrained.

# IµS for Small Angle X-ray Scattering

The IµS was integrated in the Bruker Nanostar, an equipment for SAXS and simultaneous WAXS measurements with a 3-pinhole geometry. The beam was collimated using a Quazar optics with a low divergence of 1 mrad or smaller.

### in-situ GISAXS with Liquid Samples

For rapid GISAXS measurements of liquid samples our  $I\mu$ S was combined with a Dectris Pilatus detector. The set-up can be changed from liquids to capillary samples within <30 min, alignment included (picture and data courtesy of P. Šiffalovič, Slovak Academy of Science). The measurement shows an ordering of the particles. It was possible to study the evolution of the ordering with increasing surface pressure in-situ.

### GISAXS

With the I $\mu$ S GISAXS measurements of high data quality can also be carried out in the lab. The figure shows the results of an ion-beam sputtered Mo/ Si multilayer. The total reflection and three Bragg sheets are clearly visible.

## Highly Absorbing Crystals

In Ag radiation the I $\mu$ S delivers a peak flux density of about 0.9 x 10° photons/(s mm<sup>2</sup>) in a 90  $\mu$ m beam (FWHM), which is ideal for small crystals, especially of absorbing materials. The advantage of such short wavelengths is the reduced absorption and extinction, as well as the "compressed" reciprocal space thus gaining access to a larger range of *d*-spacings at a fixed  $2\theta$  setting. The figure shows the comparison of two single crystal diffraction experiments with the Ag-I $\mu$ S and the Mo-I $\mu$ S on an organic sample.

Residual density and the resolution limit (at  $2\theta = 31^{\circ}$ ; DX = 51 mm) for  $C_{26}H_{19}PS$ : Ag-IµS (200 s/°, left), Mo-IµS (77 s/°, right) (data from F.P.A. Fabbiani, University Göttingen, Germany)

Sample: Langmuir film with silver nanoparticles the surface was pressed with 26mN/m
